ABSTRACT

Background: Plastibell circumcision is safe alternative to open circumcision. Objective: The aim of this study is to review the safety and complications of plastibell circumcision as compared to other techniques reported in literature. Study Design: Retrospective Observational study. Settings: Private Sector Hospital, Faisalabad. Duration: January 2008 to December 2017. Methodology: 2576 cases including neonates and children up to 5 years of age circumcised in private clinic. Results: In 98.5% of cases there was no complication. In 1.5% of the cases complications like hematoma, bleeding, slipped ligature, retention of bell, urinary retention, infection and unsatisfactory results with less amount of prepural skin being removed were encountered. Conclusion: Plastibell circumcision is a safe technique with minimum complications in experienced hands and good alternative to open technique.

Keywords: Plastibell, Circumcision, Neonates.

INTRODUCTION

Circumcision is surgical removal of prepuce that covers the glans penis. Circumcision is a desirable public health intervention and an old custom being practiced in various communities for a long time. It is one of the most common male surgical procedure performed globally with one in three males circumcised worldwide. It is performed in Muslim and Jewish communities as a religious tradition with almost two-thirds of circumcised males worldwide being Muslims. There are clear advantages of early circumcision, preferably during the neonatal period with a clear correlation between complications and increasing age. The advantages include decreased incidence of urinary tract infections (UTI), faster healing, lower complication rate and cost effectiveness. The benefits also include reduced chance of HIV acquisition, HPV, penile warts, penile cancer and improved personal hygiene.

There are different methods of pediatric circumcision e.g. the dorsal slit method, the Plastibell method, the Gomco clamp and the Mogen shield or clamp. In infants the penis is small with a relatively undeveloped blood supply and post-operative penile erections are not a significant factor and these may be reasons why there has been widespread use of all these devices in infant circumcision in various countries but their use in adults remains experimental.

The plastibell is a stay on disposable plastic ring with handle which is tightly tied on the foreskin and becomes detached and falls off naturally leaving a neat result and it comes in different sizes. Its use was first reported in 1956. It is quick and effective method to achieve hemostasis and safe and easy to perform in infants using only local anesthesia with very few associated complications. Complications range from minor events such as oedema, surgical site infections, residual foreskin and retained ring to major complications such as ring slippage with primary hemorrhage, glansular gangrene and urethrocutaneous fistula.

The aim of this paper is to review the complications of Plastibell circumcision reported in the literature and to review our own complications and to emphasize that it is a safe technique for circumcision with very low complication rate.

METHODOLOGY

Study Design: Retrospective Observational study.
Settings: Private Sector Hospital, Faisalabad.
Duration: January 2008 to December 2017.
Sample Technique: Simple random sampling technique.
Sample Size: 2576 patients.
Inclusion Criteria: All healthy neonates and children up to 5 years of age were included.
Exclusion Criteria: Neonates and children with Hypospadias, Epispadias, Webbed penis, Neonatal jaundice and congenital bleeding disorders are excluded from the study.

Data Collection Procedure: In this study neonates and children were operated by team of consultant surgeons. Preoperative examination, consent taking and explanation of procedure to the parents was done by operating surgeon. The baby identified and restrained. The penis prepared with an antiseptic solution and local anesthesia dose of 1% Bupivacaine was calculated according to weight provided as penile block. The preputial ring dilated with a hemostat, foreskin retracted, all smegma removed and cleaned. Soft adhesions between glans and prepuce separated and the urethral meatus definitely identified. The foreskin grasped with hemostats at 10, 2 and 6 o’clock positions. A dorsal slit made at 12 o’clock position. The correct size Plastibell selected. The foreskin is pulled over the
Plastibell which was stabilized by a hemostat clamping the skin to the handle of the Plastibell. The ligature applied on the Plastibell groove using a surgeon’s knot for the first throw. The foreskin excised just past the outermost edge of the Plastibell taking care not to damage the glans. Final checking for bleeding, meatal opening and correct position of the ligature was performed at the end of the procedure. Post-operative Panadol drops were advised for pain relief. No antibiotics were prescribed. The parents were advised to watch for complications and strongly encouraged to come back to hospital in case of any problems and they were given contact numbers for any queries. The data of complications was collected from record of emergency visits of patients.

RESULTS

In our setup circumcisions are performed as part of religious custom. The size of Plastibell ring ranges from 1.1cm to 1.7 cm. Most common size used was 1.3cm (43%) and next common being 1.4cm (36%). Least used size was 1.7cm (1%) (Table 1). Most circumcisions were performed in neonates (Table 2). On preoperative examination of the infants with hypospadias, local infection, systemic illness and physiological jaundice were excluded from the study. In two children of 4.5 and 5 years of age there was slippage of ligature and in both cases, it was reapplied. In seven cases there was hemorrhage due to peeling off of inner layer and converted to open circumcision. There was retention of bell in 5 cases which was removed manually. In five cases there was inadequate excision of foreskin and revision was done again by using plastibell. In four cases there was retention of urine and required emptying of bladder with fine catheter. In twenty cases mild infection was encountered with include indurated margins, edema of proximal skin and serous exudate from margins. In these cases, topical antiseptic cream containing fusidic acid was advised. In one febrile child of five years of age with local infection oral antibiotic syrup was also given.

Steps of plastibell circumcision

- Holding of foreskin at 3 points
- Making the dorsal slit
- Tying up the ligature
- Excising the redundant skin
- Final appearance

Different sizes of plastibell

DISCUSSION

Plastibell circumcision is a safe and simple method for circumcision in neonates and children. There are many reasons to perform circumcision e.g. therapeutic, prophylactic, religious, cultural or social reasons. In our study 100% of the circumcisions were performed as a religious ritual. Studies conducted by Bioku Muftau Jimoh et al and Okechukwu Hyginus Ekwnufe et al the religious indication for circumcision was 53% and 59.3% respectively and cultural reason was 47% and 36.2% respectively. We found out that the most common plastibell size deployed was 1.3cm (43%) while 1.7cm was the least commonly used ring (1%). These results are similar to those reported by Bioku Muftau Jimoh et al, most common size used was 1.3cm (45.7%) and least common was 1.6cm (0.4%). Complication rate of this procedure varies from 0.9% to 3.1% and can be up to 20% in some studies. Complication rate of conventional circumcision in literature is 3%, and in our study the complication rate is 1.5% which is almost half of the conventional circumcision complication rate and falls in lower range of complication rate of plastibell circumcision. There are many complications reported in the literature such as proximal migration of the bell on to the distal penile shaft causing compression, hemorrhage, slippage of ligature, denudation of penile skin, necrotizing fasciitis and dreadful complication of rupture of bladder due to urinary obstruction by the Plastibell. In our study infection is the most common complication (0.7%) followed by hemorrhage (0.27%) which differs from literature in which hemorrhage is the most common complication. The rate of infection is less than that reported by Seyed Abdullah Mousavi et al (1%) and Carolina Talini et al (1.2%). It is also less than the rate of infection in conventional circumcision reported in literature (4%-14.9%). The rate of hemorrhage in our study is 0.27% which is less than that reported by Carolina Talini et al (32.9%), Seyed Abdullah Mousavi et al (18%) Bioku Muftau Jimoh et al (48%) and Sajid Razzaq et al (2.8%). It is also significantly less than the rate of hemorrhage in conventional circumcision reported in literature (35%). Complication of Penile stenosis is not reported in our study but study done by Sajid Razzaq et al, its rate is 22.8%. The dreadful complication of urethral injury reported in literature by Okechukwu Hyginus Ekwnufe et al (0.7%) was not observed in our study. In our study redo circumcision was done in 5 cases due to inadequate foreskin removal and results are similar to those of Rebeca M Plank, MD et al in which 4 cases underwent redo circumcision.

CONCLUSION

Plastibell circumcision is a safe procedure in experienced hands with few complications. Other than neonates it can be safely performed in older individual as well.

LIMITATIONS

At times there are problems with the availability of different sizes of Plastibell.

SUGGESTIONS / RECOMMENDATIONS

Local manufacturing of Plastibell can solve the issue of unavailability of plastibell.

CONFLICT OF INTEREST / DISCLOSURE

None.

ACKNOWLEDGEMENTS

We acknowledge the administration of Saad Surgimed Hospital, Faisalabad for their help in collection and provision of data.
